## ABSTRACT

The purpose of this paper is to give a general and a simple approach to describe the Sylow r-subgroups of classical groups.

Key words: Sylow r-subgroups, wreath product.2000 Mathematics Subject Classification: 20D15.

# Introduction

Let G be a finite classical group over a finite field of characteristic p. The Sylow r-subgroups of G, where r is a prime number, have been given by Weir [5] in the case  $r \neq 2, r \neq p$ , and by Chevalley [3] and Ree [4] in the case r = p. In the later case the normalizers of the Sylow p-subgroups were obtained as well. The remaining case  $r = 2, p \neq 2$  has been investigated by Carter and Fong [2], where the description is not easy to follow.

ISSN: 1139-1138 http://dx.doi.org/10.5209/rev\_REMA.2005.v18.n2.16676 The main purpose of this paper is to give a more general and simple approach to describe the Sylow r-subgroups of the general linear group  $\operatorname{GL}(n,q)$ , the symplectic group  $\operatorname{Sp}(2n,q)$  over  $\operatorname{GF}(q)$ ,  $q = p^a$ , and the symmetric group  $S_n$ , using number theoretic techniques, so that general readers simply can read it. Among other results the conditions on r and G forcing the Sylow r-subgroups of  $\operatorname{GL}(n,q)$  to be maximal nilpotent are given.

Let V be a n-dimensional vector space over GF(q). In the case of GL(V) = GL(n,q), if d is a divisor of n, we consider the set  $\{V_1, V_2, \ldots, V_m\}$  of d-dimensional subspaces such that  $V = V_1 \oplus V_2 \oplus \cdots \oplus V_m$ , where m = n/d. Then the stabilizer of this set in GL(V) is obviously a wreath-product  $GL(V_1) \wr S_m$ . Then we show that for any prime  $r \neq p$ , the number d can be chosen in such a way that this stabilizer contains a Sylow r-subgroup. Hence the Sylow r-subgroups are of the form  $R \wr T_m \leq GL(V_1) \wr S_M$ , where R is a Sylow r-subgroup of  $GL(V_1)$  and  $T_m$  is a Sylow r-subgroup of  $S_m$ . From this description the action of the Sylow r-subgroups on the underlying vector space are obvious.

The approach for the other classical groups is quite similar. Let V be a vector space endowed with a bilinear, unitary or quadratic form. Then we consider an orthogonal decomposition  $V = V_1 \perp V_2 \perp \cdots \perp V_m$  into non-degenerate subspaces of equal dimension d say. The stabilizer of the set  $\{V_1, V_2, \ldots, V_m\}$  is then obviously isomorphic to  $I(V_1) \wr S_m$ , where  $I(V_1)$  denotes the isometry group of  $V_1$ . Again by choosing d properly we find the Sylow r-subgroups are contained in such stabilizer and hence are isomorphic to  $R \wr T_m$  where R is a Sylow r-subgroup of  $I(V_1)$  and  $T_m$ is a Sylow r-subgroup of  $S_m$ . Also the action on the underlying vector space can be immediately seen.

#### 1. Notation and basic definitions

Let *n* be an integer, *p* prime, we denote by  $n_p$  the *p* part of *n*. If *G* is a finite group, then |G| denotes the order of *G*. If *p* is prime  $\mathbb{Z}_{p-1}$  will denote the multiplicative cyclic group  $(\mathbb{Z}/p\mathbb{Z})^*$  of the finite field GF(p). If  $g \in G$ , o(g) denotes the order of *g*. Throughout the paper *r*, *p* are primes,  $r \neq p$ , and  $q = p^a$ .  $H \wr K$  denotes the wreath product of *H* by *K*. For more information about the wreath product see [1]. [H:K]denotes the index of *K* in *H*. We write  $X^m$  for a direct product of *m* copies of *X*.

## 2. The Sylow *r*-subgroups of GL(n, q)

To investigate the Sylow r-subgroups of GL(n,q), we prove the following Lemmata which are of fundamental importance in this investigation.

**Lemma 2.1.** Let d be the order of  $q + r\mathbb{Z} \in (\mathbb{Z}/r\mathbb{Z})^*$ , then  $(q^i - 1)_r \neq 1$  if and only if  $d \mid i$ .

Revista Matemática Complutense 2005, 18; Núm. 2, 329–338

*Proof.* Since  $|\operatorname{GL}(n,q)| = q^{\binom{n}{2}} \prod_{i=1}^{n} (q^i - 1)$ , we have  $|\operatorname{GL}(n,q)|_r = \prod_{i=1}^{n} (q^i - 1)_r$ . It is clear that  $r \mid q^i - 1$  if and only if  $(q + r\mathbb{Z})^i = 1 + r\mathbb{Z}$ , and  $(q + r\mathbb{Z})^i = 1 + r\mathbb{Z}$  iff  $d \mid i$ . Hence the Lemma is proved.

**Lemma 2.2.** If  $r \mid q-1$ , then the following properties hold:

- (i) If  $r \neq 2$ , then  $(q^i 1)_r = i_r(q 1)_r$ .
- (ii) If r = 2 and  $q \equiv 1 \pmod{4}$ , then  $(q^i 1)_2 = i_2(q 1)_2$ .
- (iii) If r = 2, and  $q \equiv 3 \pmod{4}$ , then

$$(q^{i} - 1)_{2} = \begin{cases} 2, & \text{if } i \text{ is odd,} \\ i_{2}(q+1)_{2} & \text{if } i \text{ is even.} \end{cases}$$

*Proof.* Since  $r \mid q-1$  we write  $q = 1 + r^a x$  for  $a \ge 1$  and gcd(r, x) = 1. On the other hand,  $q^i - 1 = (q-1)(1+q+\cdots+q^{i-1})$  implies  $(q^i - 1)_r = (q-1)_r(1+q+\cdots+q^{i-1})_r$ . Since  $q \equiv 1 \pmod{r}$  then  $1 + q + \cdots + q^{i-1} \equiv i \pmod{r}$ .

- (i) Case 1:  $r \nmid i$ . Then  $(1 + q + \dots + q^{i-1})_r = 1$  and we are done.
- Case 2: r|i. So  $i = r^b j$  with gcd(j, r) = 1. We need to prove that  $(1 + q + \dots + q^{i-1})_r = r^b$ .

Since  $q^i - 1 = q^{r^b j} - 1 = (q^j - 1)(q^{j(r^b - 1)} + \dots + q^{2j} + q^j + 1)$  then  $(q^i - 1)_r = (q^j - 1)_r(q^{j(r^b - 1)} + \dots + q^j + 1)_r = (q - 1)_r(q^{j(r^b - 1)} + \dots + q^j + 1)_r)$ , by case 1. We have also  $q^{j(r^b - k)} = (1 + r^a x)^{j(r^b - k)} \equiv 1 + j(r^b - k)r^q x \pmod{r^{2a}}$ . Thus,

$$1 + \sum_{k=1}^{r^b - 1} q^{j(r^b - k)} \equiv r^b \Big( 1 + jr^a x(r^b - 1) - jr^a x \frac{r^b - 1}{2} \Big) \pmod{r^{2a}}$$

because  $r \neq 2$ . Therefore

$$(1+q^j+\cdots+q^{j(r^b-1)})_r=r^b.$$

(ii) We consider the following two cases:

- Case 1: *i* is odd. Then  $1 + q + \dots + q^{i-1}$  is odd, and this implies  $(q^i 1)_2 = (q-1)_2(1+q+\dots+q^{i-1})_2 = (q-1)_2 = i_2(q-1)_2$ .
- Case 2: *i* is even. So i = 2j and  $(q^i 1)_2 = (q^{2j} 1)_2 = (q^j 1)_2(q^j + 1)_2$ . Since  $q \equiv 1 \pmod{4}$  this implies  $q^j + 1 \equiv 2 \pmod{4}$ . Hence  $(q^i 1)_2 = (q^j 1)_2 \cdot 2 = j_2(q 1)_2 \cdot 2 = i_2(q 1)_2$  by induction.
  - (iii) Again we have two cases:

Revista Matemática Complutense 2005, 18; Núm. 2, 329–338

Case 1: *i* is odd. Then  $(q^i - 1)_2 = (q - 1)_2(1 + q + \dots + q^{i-1})_2 = (q - 1)_2 = 2$ . since  $a^2 = 1 \pmod{4}$  then by (ii) we have  $(a^i - 1)$ 

Case 2: *i* is even. So 
$$i = 2j$$
 and since  $q^2 \equiv 1 \pmod{4}$ , then by (ii) we have  $(q^i - 1)_2 = (q^{2j} - 1)_2 = j_2(q^2 - 1)_2 = j_2(q - 1)_2(q + 1)_2 = j_2 \cdot 2 \cdot (q + 1)_2 = i_2(q + 1)_2$ .  $\Box$ 

**Lemma 2.3.** Let r and p be distinct primes,  $q = p^a$ , and  $d = o(q + r\mathbb{Z})$  where  $q + r\mathbb{Z} \in (\mathbb{Z}/r\mathbb{Z})^*$  then the following properties hold:

- (i) If either  $r \neq 2 \text{ or } r = 2 \text{ and } q \equiv 1 \pmod{4}$ , then  $|\operatorname{GL}(n,q)|_r = (q^d 1)_r^{\left[\frac{n}{r}\right]}([\frac{n}{d}]!)_r$ .
- (ii) If r = 2,  $q \equiv 3 \pmod{4}$  and n is even, then  $|\operatorname{GL}(n,q)|_r = (2^2(q+1)_2)^{\frac{n}{2}}((n/2)!)_2$ .

(iii) If r = 2,  $q \equiv 3 \pmod{4}$  and n is odd, then

$$|\operatorname{GL}(n,q)|_r = 2\left(2^{n-1}\prod_{\substack{i\leq n\\i \ even}} i_2(q+1)_2\right).$$

*Proof.* (i) We have

$$|\operatorname{GL}(n,q)|_r = \left|q^{\binom{n}{2}}\prod_{i=1}^n (q^i-1)\right|_r = \prod_{i=1}^n (q^i-1)_r = \prod_{i\leq n,\ d|i} (q^i-1)_r.$$

By Lemma 2.1,  $r \mid q^i - 1$  iff  $d \mid i$ . We obtain  $\prod_{i \leq n, d \mid i} (q^i - 1)_r = \prod_{j=1}^{\lfloor \frac{n}{d} \rfloor} (q^{dj} - 1)_r$  and by Lemma 2.2, with q replaced by  $q^d$ , we obtain

$$\prod_{j=1}^{\left[\frac{n}{d}\right]} (q^{dj} - 1)_r = \prod_{j=1}^{\left[\frac{n}{d}\right]} j_r (q^d - 1)_r = (q^d - 1)_r^{\left[\frac{n}{d}\right]} \prod_{j=1}^{\left[\frac{n}{d}\right]} j_r = (q^d - 1)_r^{\left[\frac{n}{d}\right]} \left(\left[\frac{n}{d}\right]!\right)_r.$$

Hence a Sylow r-subgroup of  $\operatorname{GL}(n,q)$  is isomorphic to  $Z_{(q^d-1)_r} \wr T_{\left[\frac{n}{d}\right]}$ , where  $T_{\left[\frac{n}{d}\right]}$  is

a Sylow *r*-subgroup of  $S_{\left[\frac{n}{d}\right]}$ . (ii)  $|\operatorname{GL}(n,q)|_2 = \prod_{i=1}^{n} (q^i - 1)_2$ . Let  $n = 2n_1$  for some integer  $n_1$ , then we have

$$\prod_{i=1}^{n} (q^{i} - 1)_{2} = \prod_{j=0}^{n-1} (q^{2j+1} - 1)_{2} \prod_{j=1}^{n_{1}} (q^{2j} - 1)_{2} =$$

$$= 2^{n/2} \prod_{j=1}^{n/2} (q^{2j} - 1)_{2} = 2^{n/2} \prod_{j=1}^{n/2} (2j)_{2} (q+1)_{2} =$$

$$= 2^{n} (q+1)_{2}^{n/2} \prod_{j=1}^{n/2} j_{2} = 2^{n} (q+1)_{2}^{n/2} (n/2)! = (2^{2} (q+1)_{2})^{n/2} ((n/2)!)_{2}.$$

Revista Matemática Complutense 2005, 18; Núm. 2, 329-338

Hence if n is even and  $q \equiv 3 \pmod{4}$ , then a Sylow 2-subgroup of  $\operatorname{GL}(n,q)$  is isomorphic to  $D \wr T$  where D is a Sylow 2-subgroup of  $\operatorname{GL}(2,q)$  and T is a Sylow 2-subgroup of the symmetric group  $S_{n/2}$ .

(iii) We have

$$|\operatorname{GL}(n,q)|_{2} = \prod_{i=1}^{n} (q^{i}-1)_{2} = \prod_{\substack{i \leq n \\ i \text{ odd}}} 2 \prod_{\substack{i \leq n \\ i \text{ even}}} (q^{i}-1) =$$
$$= 2^{n} \prod_{\substack{i \leq n \\ i \text{ even}}} i_{2}(q+1)_{2} = 2 \cdot 2^{n-1} \prod_{\substack{i \leq n \\ i \text{ even}}} i_{2}(q+1)_{2}$$

Hence, if n is odd and  $q \equiv 3 \pmod{4}$ , then a Sylow 2-subgroup of  $\operatorname{GL}(n, q)$  is isomorphic to  $Z_2 \times S \leq \operatorname{GL}(1, q) \times \operatorname{GL}(n - 1, q) \leq \operatorname{GL}(n, q)$ , where S is a Sylow 2-subgroup of  $\operatorname{GL}(n - 1, q)$ . The Sylow r-subgroups of  $S_n$  will be discussed in section 4.  $\Box$ 

Combining Lemma 2.1 and Lemma 2.2 we have

**Lemma 2.4.** Let r and p be distinct primes,  $q = p^a$ . Define  $d = o(q + r\mathbb{Z})$  where  $q + r\mathbb{Z} \in (\mathbb{Z}/r\mathbb{Z})^*$ , then we have

- (i)  $r \mid q^i 1$  iff  $d \mid i$ .
- (ii) If  $d \mid i$  and either  $r \neq 2$ , or r = 2 and  $q \equiv 1 \pmod{4}$ , then  $(q^i 1)_r = (\frac{i}{d})_r (q^d 1)_r$ .
- (iii) If  $d \mid i, r = 2$ , and  $q \equiv 3 \pmod{4}$ , then

$$(q^{i}-1)_{r} = \begin{cases} 2, & \text{if } i \text{ is odd,} \\ i_{2}(q+1)_{2}, & \text{if } i \text{ is even.} \end{cases}$$

Remark 2.5. For  $\operatorname{GL}(n,q)$  there are obviously subgroups of the orders calculated above.  $\operatorname{GL}(n,q)$  contains the group of the monomial matrices  $M \cong Z_{q-1} \wr S_n$ . So in the case  $r \mid q-1$ , M contains a Sylow r-subgroup. In general, set  $d = o(q + r\mathbb{Z})$ and write  $n = n_0d + n_1$  for integers  $n_0$ ,  $n_1$  with  $0 \leq n_1 < d$ , then we have a canonical embedding of  $\operatorname{GL}(n_0d,q)$  into  $\operatorname{GL}(n,q)$  as follows. Let V be a vector space of dimension n over  $\operatorname{GF}(q)$  and write  $V = V_0 \oplus V_1$  where  $\dim V_0 = n_0d$ ,  $\dim V_1 = n_1$ , so, if  $H = \operatorname{GL}(V_1) \times \operatorname{GL}(V_0)$ , then  $C_H(V_0) \cong \operatorname{GL}(V_1) = \operatorname{GL}(n_1,q)$  and  $C_H(V) \cong$  $\operatorname{GL}(V_0) = \operatorname{GL}(n_0d,q)$ . Further, if W is a vector space of dimension  $n_0$  over  $\operatorname{GF}(q^d)$ , then W is also a vector space over a subfield  $\operatorname{GF}(q) \subseteq \operatorname{GF}(q^d)$  of dimension  $n_0d$ , hence we have a canonical embedding  $\operatorname{GL}(m_0,q^d) \subseteq \operatorname{GL}(n_0d,q) \subseteq \operatorname{GL}(n_0d,q)$ . So we get a sequence of embeddings  $\operatorname{GL}(n_0,q^d) \subseteq \operatorname{GL}(n_0d,q) \subseteq \operatorname{GL}(n_0d+n_1,q) = \operatorname{GL}(n,q)$ , and  $\operatorname{GL}(n_0,q^d)$  contains a monomial group  $M^* \cong Z_{q^d-1} \wr S_{n_0}$  which contains, as we have shown above, a Sylow r-subgroup.

## 3. The Sylow *r*-subgroups of Sp(2n, q)

To describe the Sylow r-subgroups of Sp(2n, q) we prove the following Lemmas.

**Lemma 3.1.** Let r and p be distinct primes,  $q = p^a$  and r odd, then

- (i)  $\operatorname{Sp}(2n,q)$  contains canonically a subgroup H isomorphic to  $\operatorname{GL}(n,q)$ .
- (ii) If d is odd, then r does not divide the index of H in  $\operatorname{Sp}(2n,q)$ , where  $d = o(q+\mathbb{Z})$ ,  $q + \mathbb{Z} \in (\mathbb{Z}/r\mathbb{Z})^*$ .
- (iii) Any canonically embedded GL(n,q) contains a Sylow r-subgroup of Sp(2n,q).

*Proof.* (i) Consider a symplectic base with respect to which the inner product matrix is  $\begin{bmatrix} 0 & I \\ -I & 0 \end{bmatrix}$ . Then the subgroup

$$H = \left\{ \begin{bmatrix} g & \\ & (g^t)^{-1} \end{bmatrix}, \quad g \in \operatorname{GL}(n,q) \right\}$$

is contained in the corresponding symplectic group  $\mathrm{Sp}(2n,q).$ 

The index of H in Sp(2n,q) is

$$\frac{q^{n^2}\prod_{i=1}^n (q^{2i}-1)}{q^{\binom{n}{2}}\prod_{i=1}^n (q^i-1)} = q^{n(n+1)/2} \prod_{i=1}^n (q^i+1).$$

(ii) Assume that  $r \mid q^{n(n+1)/2} \prod_{i=1}^{n} (q^i+1)$ . This implies that  $r \mid q^i+1$  for some  $1 \leq i \leq n$ , so  $r \mid q^{2i} - 1$ . This means that  $q^{2i} \equiv 1 \pmod{r}$ , thus  $d \mid 2i$ . As d is odd, this implies that  $q^i \equiv 1 \pmod{r}$ . Hence  $r \mid q^i+1$  and  $r \mid q^i-1$ , thus  $r \mid 2$ , a contradiction.

(iii) As  $r \nmid [\operatorname{Sp}(2n,q) : H]$ , then H contains a Sylow r-subgroup and the Sylow r-subgroups of  $\operatorname{GL}(n,q)$  have been determined in section 2.

Remark 3.2. If  $n = n_1 + n_2$ , then  $\operatorname{Sp}(2n, q)$  contains a canonically embedded subgroup  $\operatorname{Sp}(2n_1, q) \times \operatorname{Sp}(2n_2, q)$ . This can be seen as follows. If  $V_1$  and  $V_2$  are symplectic spaces, then  $V_1 \oplus V_2$  can be turned into a symplectic space, such that  $V_1$  and  $V_2$  are orthogonal. Let  $\beta_i$  be a symplectic form on  $V_i$ , i = 1, 2. Define a symplectic form  $\beta$  on  $V_1 \oplus V_2$  by  $\beta(v_1 + v_2, v'_1 + v'_2) = \beta_1(v_1, v'_1) + \beta_2(v_2, v'_2)$  where  $v_i, v'_i \in V_i$ . At the same time, this defines an embedding of  $\operatorname{Sp}(V_1) \times \operatorname{Sp}(V_2)$  into  $\operatorname{Sp}(V_1 \perp V_2)$ . Here  $V_1 \perp V_2$  denotes that  $V_1$  and  $V_2$  are orthogonal by the action

$$(v_1, v_2)^{(g_1, g_2)} = (v_1^{g_1}, v_2^{g_2})$$

where  $v_1 \in V_1$ ,  $v_2 \in V_2$ , and  $g \in \operatorname{Sp}(V_1)$ ,  $g_2 \in \operatorname{Sp}(V_2)$ . So we have a canonical embedding  $\operatorname{Sp}(2n_1, q) \times \operatorname{Sp}(2n_2, q) \subseteq \operatorname{Sp}(2(n_1 + n_2), q)$ . Repeating this process we get an embedding

$$\operatorname{Sp}(2n_1, q) \times \operatorname{Sp}(2n_2, q) \times \cdots \times \operatorname{Sp}(2n_k, q) \subseteq \operatorname{Sp}(2(n_1 + n_2 + \cdots + n_k), q),$$

for any  $n_i \neq 0$ . We have also an embedding  $\operatorname{Sp}(2n,q)^k \subseteq \operatorname{Sp}(2nk,q)$ .

Revista Matemática Complutense 2005, 18; Núm. 2, 329–338

M. I. AlAli/C. Hering/A. Neumann

The following Lemma is an immediate consequence of the above remark.

**Lemma 3.3.** Let W be a symplectic space, and assume that W can be written as an orthogonal direct sum of  $V_1 \perp V_2 \perp \cdots \perp V_k$  of subspaces  $V_i$  all of the same dimension. Let H be the stabilizer of  $\{V_1, V_2, \ldots, V_k\}$  in Sp(W), then  $H \cong$  Sp $(V_1)\wr S_k$ .

**Lemma 3.4.** Let r and p be distinct primes,  $q = p^a$ . Let  $d = o(q + r\mathbb{Z})$  where  $q + r\mathbb{Z} \in \mathbb{Z}_{r-1}$ . If d is even, then

$$|\operatorname{Sp}(2n,q)|_r = (q^d - 1)_r^{\left[\frac{2n}{d}\right]} \left( \left[\frac{2n}{d}\right]! \right)_r$$

*Proof.* Let d = 2t for some integer t. Then

$$|\operatorname{Sp}(2n,q)|_r = \prod_{i=1}^n (q^{2i} - 1)_r = \prod_{\substack{i=1\\d|2i}}^n (q^2i - 1)_r = \prod_{\substack{i=1\\t|i}}^n (q^{2i} - 1)_r$$

By setting i = tj we have

$$\prod_{i=1\atop t\mid i}^{n} (q^{2i-1})_r = \prod_{j=1}^{\left[\frac{n}{t}\right]} (q^{dj} - 1)_r.$$

By Lemma 2.4, we obtain

$$\begin{split} \prod_{j=1}^{\left[\frac{n}{t}\right]} j_r (q^d - 1)_r &= (q^d - 1)_r^{\left[\frac{n}{t}\right]} \prod_{j=1}^{\left[\frac{n}{t}\right]} j_r = (q^d - 1)_r^{\left[\frac{n}{t}\right]} \left( \left[\frac{n}{t}\right]! \right)_r = \\ &= (q^d - 1)_r^{\left[\frac{2n}{d}\right]} \left( \left[\frac{2n}{d}\right]! \right)_r. \end{split}$$

**Theorem 3.5.** Let r be an odd prime,  $r \neq p$ ,  $q = p^a$ , and  $d = o(q + r\mathbb{Z})$ . Then the following hold:

- (i) If d is odd, then any canonically embedded GL(n,q) contains a Sylow r-subgroup of Sp(2n,q).
- (ii) If d is even, d = 2t for  $1 \le t \le n$  and n = at + b for  $0 \le b < t$ , then any canonically embedded subgroup  $\operatorname{Sp}(2t,q) \wr S_a \times \operatorname{Sp}(2b,q)$  contains a Sylow r-subgroup of  $\operatorname{Sp}(2n,q)$  which is isomorphic to  $Z_{(q^t-1)_r} \wr T$ , where T is a Sylow r-subgroup of  $S_a$ .

*Proof.* (i) It follows from Lemma 3.1.

(ii) It is an immediate consequence of Lemma 3.3 and Remark 2.5.

Revista Matemática Complutense 2005, 18; Núm. 2, 329–338

We are left with the remaining case r = 2, which will be settled by the following theorem.

**Theorem 3.6.** The Sylow 2-subgroups of Sp(2n,q) are  $D \wr T$  where D is a Sylow 2-subgroup of Sp(2,q) = SL(2,q), T is a Sylow 2-subgroup of  $S_n$ , and q is odd.

Proof. By Lemma 2.4, we obtain

$$|\operatorname{Sp}(2n,q)|_2 = \prod_{i=1}^n (q^{2i} - 1)_2 = \prod_{i=1}^n i_2(q^2 - 1)_2 = (q^2 - 1)_2^n (n!)_2.$$

So we have an orthogonal decomposition subgroup  $\operatorname{Sp}(2,q) \wr Sn \leq \operatorname{Sp}(2n,q)$ . Hence the Sylow 2-subgroups of  $\operatorname{Sp}(2n,q)$  are as in the Theorem.  $\Box$ 

## 4. The Sylow r-subgroups of the symmetric group $S_n$

To complete the description of the Sylow r-subgroups of GL(n,q) and Sp(2n,q), we investigate the Sylow r-subgroups of  $S_n$ . The following results are useful.

**Lemma 4.1.** Let r and p be different primes. If n = pm + r,  $0 \le r < p$ . Then  $(n!)_p = p^m([\frac{n}{p}]!)_p$ .

*Proof.* We have the identities

$$(n!)_p = \prod_{i=1}^n i_p = \prod_{j=1}^{\left[\frac{n}{p}\right]} (jp)_p = \prod_{j=1}^{\left[\frac{n}{p}\right]} pj_p = p^{\left[\frac{n}{p}\right]} \prod_{j=1}^{\left[\frac{n}{p}\right]} j_p = p^{\left[\frac{n}{p}\right]} (\left[\frac{n}{p}\right]!)_p. \qquad \Box$$

**Corollary 4.2.** A Sylow p-subgroup of  $S_n$  is isomorphic to  $Z_p \wr T$ , where  $Z_p$  is a Sylow p-subgroup of  $S_p$  and T is a Sylow p-subgroup of  $S_m$ .

**Theorem 4.3.** If  $T_n$  is a Sylow p-subgroup of  $S_n$ , then  $T_n = Z_p \wr (Z_p \wr (Z_p \wr T_{[n/p^3]}))$ . (It is a recursive relation.)

Proof. Let  $S_n$  act on a set  $\Omega$  of size n. Let n = pm + r, where  $0 \le r < p$ . Consider a partition of  $\Omega$  by the sets  $A_1, A_2, \ldots, A_m$ ,  $\Gamma$ , where  $|A_i| = p$  and  $|\Gamma| = r$ . We have that  $\Omega = \bigcup_{i=1}^m A_i \cup \Gamma$  is a disjoint union. The stabilizer of this partition in  $S_n$  is  $H = (S_p \wr S_m) \times S_r$ , which contains a subgroup  $S = Z_p \wr T$  where  $Z_p$  is a Sylow p-subgroup of  $S_p$  and T is a Sylow p-subgroup of  $S_m$ . By changing the orders we see that if  $T_n$  is a Sylow p-subgroup of  $S_n$ , then  $T_n = Z_p \wr T_{[n/p]}$  where  $T_{[n/p]}$ is a Sylow p-subgroup of  $S_{[n/p]}$ , and  $T_{[n/p]} = Z_p \wr T_{[[n/p]/p]} = Z_p \wr T_{[n/p^2]}$ . Hence  $T_n = Z_p \wr (Z_p \wr T_{[n/p^2]}) = Z_p \wr (Z_p \wr (Z_p \wr T_{[n/p^3]}))$ . It is a recursive relation.  $\Box$

## 5. A question

What are the conditions on r and q that force the Sylow r-subgroups of GL(n,q) to be maximal nilpotent? To answer this question we prove the following theorem.

**Theorem 5.1.** Let r, p be two distinct primes,  $d = o(q+r\mathbb{Z})$  where  $q+r\mathbb{Z} \in (\mathbb{Z}/r\mathbb{Z})^*$ . Suppose that n = md+k,  $0 \le k < d$ , and R is a Sylow r-subgroup of  $\operatorname{GL}(n,q)$ . If R is maximal nilpotent, then  $n \equiv 0, 1 \pmod{d}$  and  $q^d - 1 = r^i$  for some positive integer i.

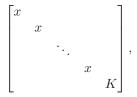

*Proof.* Let S be a Sylow r-subgroup of GL(d,q). By Schur's Lemma S is cyclic and  $|S| = (q^d - 1)_r$ . If R is a Sylow r-subgroup of GL(n,q), then  $R = S \wr T$  where T is a Sylow r-subgroup of  $S_m$ .

In a matrix form,

$$S = \left\{ \begin{bmatrix} x_1 & & & \\ & x_2 & & \\ & & \ddots & \\ & & & x_m & \\ & & & & I \end{bmatrix} \middle| \begin{array}{c} x_i \in S \\ x_i \in S \\ \end{array} \right\},$$

where  $x_i$  is a  $d \times d$  matrix and I is the identity  $k \times k$  matrix. Now we prove that  $C_{\mathrm{GL}(n,q)}(R)$  is contained in R if R is maximal nilpotent.

Let  $x \in C_{\mathrm{GL}(n,q)}(R)$ . This implies that  $\langle R, x \rangle$  is again nilpotent. Since R is maximal nilpotent, it follows that  $R = \langle R, x \rangle$ . Thus  $x \in R$ . It is obvious that all elements

where K is any  $k \times k$  matrix and  $x \in C_{\mathrm{GL}(d,k)}(S)$ , are contained in  $C_{\mathrm{GL}(n,q)}(R)$ . So if R is maximal nilpotent, all these elements must be contained in R. Finally, set

$$U = \left\{ \begin{bmatrix} x & & & \\ & x & & \\ & & \ddots & \\ & & & x \\ & & & & K \end{bmatrix} \middle| x \in C_{\mathrm{GL}(d,q)}(S), \quad K \in \mathrm{GL}(k,q) \right\}.$$

Then  $U \leq C_{GL(n,q)}(R)$ . So, if R is maximal nilpotent, this implies  $U \leq R$  and hence U must be a r-group. Thus  $|U| = |C_{GL(d,q)}(S)| |GL(k,q)| = (q^d - 1)|GL(k,q)|$  must be a power of r. Thus  $d^q - 1 = r^i$  and  $|GL(k,q)| = r^j$ , this implies, k must be at most 1, hence k = 0 or 1, which means  $n \equiv 0, 1 \pmod{d}$ .
